

STEREO POWER AMPLIFIER

SPEC-4

SERVICE MANUAL

MODEL SPEC-4 COMES IN TWO VERSIONS DISTINGUISHED AS FOLLOWS:

Type	Voltage	Remarks
KU	120V only	U. S. A. model
S	110V, 120V, 220V and 240V (Switchable)	General export model

- This service manual is applicable to KU(p2—p40) and S(p41—p48) types.
- For servicing of S type please refer to KU type with the exception of descriptions in the Additional Service Manual (p41—p48).

Power Amplifier

Circuitry Current mirror loaded differential Amplifier,
3-stage darlington parallel push-pull, direct-coupled OCL.

Continuous Power Output from 20 Hertz to 20,000 Hertz
(Both channels driven) . . . 180 watts per channel (4 ohms)
150 watts per channel (8 ohms)

Total Harmonic Distortion (20 Hertz to 20,000 Hertz, 8 ohms)

Continuous rated power output 0.01%

75 watts per channel power output 0.01%

1 watt per channel power output 0.01%

Intermodulation Distortion (50 Hertz: 7,000 Hertz=4:1, 8 ohms)

Continuous rated power output 0.01%

75 watts per channel power output 0.005%

1 watt per channel power output 0.005%

Frequency Response 5 Hertz to 100,000 Hertz $\pm 1^0$ dB

Input (Sensitivity/Impedance) 1V/50k ohms

Output

Speaker 4 ohms to 16 ohms

Damping Factor (20 Hertz to 20,000 Hertz, 8 ohms) 100

Hum and Noise (IHF, short-circuited, A network) 115dB

Miscellaneous

Power Requirements AC 120V 60 Hertz

Power Consumption 760 watts (UL)

Dimensions 480(W) x 187(H) x 445(D) mm

18-7/8 x 7-3/8 x 17-7/16 in

Weight: Without Package 24.5kg; 53lb 14oz

Furnished Parts

Connection Cord with Pin Plugs 1

Operating Instructions 1

NOTE:

Specifications and the design subject to possible modification without notice due to improvements.

2. FRONT PANEL FACILITIES

POWER SWITCH

Set to ON position to energize SPEC-4. After setting to ON, there is a brief delay before sound is obtained. This is due to the operation of the muting circuit which prevents noise when the POWER is switched. This function does not indicate difficulty and normal operating condition is attained in a several seconds.

PEAK LEVEL METERS

When speaker systems of 8ohm nominal impedance are connected, these provide direct readout of the peak output power in Watts.

NOTE:

Speaker system impedance varies according to frequency. To obtain a precise measurement of the output power, remove speaker connections and connect 8ohm dummy loads across the SPEAKER terminals.

INPUT LEVEL CONTROLS (LEFT & RIGHT)

Adjust the LEFT and RIGHT controls according to the output level (voltage) of the preamplifier connected to the SPEC-4's INPUT (L, R) terminals. If the controls are turned fully to the right (to the "0dB" position), then the rated input will be 1V. Conversely, if they are turned to the left, this will yield an attenuation equal to the graduations, and the rated power output can be varied. Standard input voltages are: 0dB = 1V, -6dB = 2V, -10dB = 3V, -12dB = 4V, and -14dB = 5V.

NOTE:

Turn the controls counterclockwise to the 0dB position if you are using a preamplifier with a maximum output voltage of less than 1V. In such cases, it will not be possible to yield the rated power output listed in the SPEC-4's specifications. (For example one-quarter of the power output is obtained with a preamplifier having a maximum output of 0.5V.)

HEXAGONAL WRENCH

Hexagonal wrench

If any of the control knobs should happen to come loose, tighten by means of the hexagonal wrench.

3. CONNECTION DIAGRAM

Before making the connections, check that the power is off. Also, make sure that you turn the power off if you want to change over the connections when the components are operating.

4 BLOCK DIAGRAM

5. CIRCUIT DESCRIPTION

5.1 POWER AMPLIFIER

This unit is a DC amplifier with an input coupling capacitor. Generally, in direct coupled amplifiers, 100% NFB is applied at the DC stage. This technique provides a DC gain of 1 and stabilizes the circuit. The operation is performed by giving the NFB circuit a time constant. However, this adversely effects the low range phase characteristics in the audio frequency range.

Careful consideration has been given to stability in the circuit design of this unit; the time constant of the low range of the NFB circuit has been eliminated, and amplification is performed up to the DC stage. This improves the low range phase characteristics and tonal quality. Moreover, the low range frequency response is determined by the time constant of the input coupling section.

The first stage is a PNP dual transistor differential amplifier with a current mirror circuit, which enables stable operation and provides high gain from the DC to the ultrahigh frequency range.

The second stage (predriver stage) is a Class A amplifier. High voltage gain is obtained by inserting a constant current circuit for the load (voltage gain is necessary at this stage because the voltage gain of the power stage is zero). The power stage is a 3-stage Darlington connection and the final stage is a parallel SEPP.

A power limiter circuit protects the power stage. D_1 , D_2 , D_3 and D_4 , D_5 , D_6 are drive voltage limiters which prevent overdriving of the power stage. D_3 , D_6 shift the DC level of the signal and D_1 , D_2 , D_4 , D_5 conduct the overdrive voltage to prevent the power stage being overdriven.

NOTE:

Since the power supply voltage of the power stage is lower than that of the drive stage at high outputs, D_1 , D_2 and D_4 , D_5 conduct the overdrive voltage.

The power limiter is a current-detection type. This limiter detects the current forced thru the power transistor by the voltage generated by the emitter resistance of the power transistors. When the output has exceeded 180W at a load of 4 ohms or less, $Q_{13} - Q_{16}$ operate to limit the drive voltage. This prevents the output from increasing even if an input greater than this is applied.

5.2 METER AMPLIFIER

A peak output meter is provided which permits direct reading of an 8 ohms load output from 0.01W to 300W.

The meter amplifier consists of the logarithmic compression circuit, absolute value detection circuit, peak hold circuit, and meter drive circuit shown in Fig. 2.

Fig. 1 Power amplifier circuit

The input signal is divided by R_1 , R_2 and sent to the logarithmic compression circuit. The logarithmic compression circuit is an audio IC (TA7136P2) and utilizes the rise characteristic of diodes D_1 , D_2 in the NFB loop to reduce the dynamic range of the signal. This creates an input/output characteristic which attenuates low level inputs very little and high level inputs substantially. The characteristic is compensated by inserting R_4 in parallel with D_1 , D_2 and the circuit is temperature compensated with a thermistor so that the meter scale is almost logarithmically graduated from 0.01W to 300W.

The compressed signal is applied to the absolute value detector. This circuit produces a reverse phase signal by means of Q_2 and extracts and combines the positive half cycle by means of Q_3 and Q_4 . This signal charges C_1 up to the peak value and drives the meter by means of Q_5 , Q_6 . The charge across C_1 is discharged at the time constant of C_1 and R_5 to determine the fall time of the peak indication of the meter.

The frequency response of the peak meter is given in Fig. 3.

5.3 PROTECTION CIRCUIT

This circuit protects the power transistors in case of overload, the speakers in case of power amplifier malfunction, and also performs a muting function when the power supply is turned ON or OFF. The protection circuit is composed of three sections (Fig. 4).

1. Relay Driver Circuit (Fig. 5)

The relay which connects the output circuits is driven by this circuit. It also performs a muting function to prevent unpleasant noise during ON-OFF operation of the power supply as well as opening the output circuit on command from the detector circuits.

Fig. 4 Block diagram of protection circuit

Fig. 2 Meter amplifier circuit

Fig. 3 Frequency response of the peak meter

Muting Operation

When the power supply is turned ON, Q_{11} base is reverse biased through D_2 and R_{22} , turning Q_{11} OFF. Q_{12} base potential rises as C_1 charges through R_1 & R_2 , and Q_{12} & Q_{13} turn ON several seconds later. The collector current of Q_{13} then flows through the relay coil, operating the relay to turn on the power amplifier output circuit. The reverse bias of Q_{11} base from D_2 & R_{22} disappears when the power supply is set from ON to OFF. Q_{11} remains ON however, due to the residual power supply voltage. C_1 very rapidly discharges, Q_{12} base potential drops and Q_{12} & Q_{13} turn OFF. The relay releases and the power amplifier output circuit turns OFF.

NOTE:

Q_{10} is normally OFF due to base bias and does not participate in the muting operation.

Fig. 5 Relay drive circuit

Operation by Detector Circuit Command

Command from the detector circuits pass through one of D_3 , D_4 or D_5 and are applied in the form of a current flow. Q_{10} is normally reverse biased through R_8 , but when a large current flows through one of these diodes, Q_{10} base potential declines according to the voltage drop at R_8 . Q_{10} then turns ON, Q_{11} base potential rises and Q_{11} turns ON. C_1 rapidly discharges and Q_{12} base potential drops, turning Q_{12} & Q_{13} OFF. The relay releases and the power amplifier output circuit becomes cut off.

2. Overload Detector Circuit

Shorting of the power amplifier load or a load impedance below the specified value causes a command to be sent to the relay drive circuit. This is illustrated in Fig. 6.

With the output stage in class B operation, when Q_a is operating in the positive half cycle, Q_b becomes cut off and the signal current flows as indicated by the solid arrows in Fig. 6. Point D potential at this time is the point A potential divided by R_{49} and R_{50} . Also, point C potential is

the point A potential divided by R_{e1} and R_L (load). Point D is connected to Q_{12} base and point C to Q_{12} emitter through R_{48} and R_{e2} . When R_L is extremely small, the point C potential becomes considerably lower than point D. This potential difference forward biases Q_{12} . Q_{12} turns ON and current flows in D_3 .

Q_b operates in the negative half cycle and Q_a becomes cut off. The signal flows is indicated by the broken line arrows in the center of Fig. 6. Q_{12} is biased by the potential difference between point C and point E. If R_L is extremely small, the point C potential becomes considerably higher than that of point E. Q_{12} turns ON and current flows in D_3 .

If large current flows in Q_a and Q_b , Q_{12} becomes ON due to the R_{e1} and R_{e2} voltage drops, and current flows in D_3 . C_{24} prevents faulty operation due to external noise.

Fig. 6 Overload detector

3. Center Point Potential Detector Circuit

If a DC potential is produced at the junction point of the power amplifier, a command is sent to the relay drive circuit. Fig. 7 shows this operating principle.

Q_8 and Q_9 compose a differential amplifier. When the same input is applied to both input terminals (Q_8 and Q_9 bases), no output is present. However, if there is a difference between the terminal inputs, the difference is amplified and becomes the output between the two collectors. During normal operation, an AC signal only is present at the junction point. As C_3 , C_4 reactance is sufficiently low, the same signal is applied to Q_8 and Q_9 bases, resulting in an absence of output at the collector sides.

When a DC potential is produced at the junction point, it becomes the input of Q_9 only. If the voltage is negative, Q_9 collector current declines.

and at Q_8 the collector current increases and the potential drops, causing current to flow through D_5 .

If the DC voltage is positive, Q_9 collector current increases and the potential drops, while at Q_8 the collector current decreases and the potential rises. Current therefore flows through D_4 .

Fig. 7 Center point potential detector

Fig. 8

5.5 OTHERS

The electrolytic capacitor ground connection is a 20mm x 2mm copper plate.

A cord (inner conductor 2.03 ϕ , 0.254 ϕ x 41 stands) having a DC resistance of about 1/4 that of common electric wire is used in the power supply, output, and ground circuits.

The input attenuator covers the 0 to -20dB range in 22 steps. The final position is $-\infty$.

5.3 POWER SUPPLY CIRCUIT

Two power transformers are used. The left channel and right channel power stage power supplies are independent. Power is supplied to each channel by a bridge rectifier and two 22,000 μ F high capacity capacitors. The power supply before the predriver and for the main amplifier, protection circuit, etc. is supplied to each part thru a bridge rectifier and minus and plus voltage regulators by connecting the windings (different from that of the power stage) of the two power transformers in series.

Surge Current Countermeasures

When the power of an amplifier having two high capacity power supplies such as this unit is turned ON, an extremely large rush current flows. The time the left and right power transformers are powered is staggered somewhat in this amplifier to reduce this rush current to a minimum.

When the power switch is turned ON, T_2 (right channel power transformer) is immediately powered, but since the relay contacts are open, T_1 (left channel power transformer) is not powered. When current flows in the coil of the relay, the relay contacts are closed and T_1 is powered. The rush current is reduced by one half during this 7-9msec delay.

6. DISASSEMBLY

Top cover

Remove the 12 screws(A) to detach the top cover.

Front panel

Loosen the set screws of the 2 LEVEL knobs with an hexagonal wrench and remove all the knobs.
Remove the 8 screws(B) and 2 nuts(D) to detach the front panel.

Bottom plate

Remove the 17 screws(C) at the bottom plate and lift off the bottom plate.

Fig. 9

7. PARTS LOCATION

8. ADJUSTMENTS

8.1 POWER AMPLIFIER

DC Balance Adjustment

Do not connect load to speaker output terminals. Set LEVEL control to minimum (fully counter-clockwise).

Adjust VR₁ for 0V at the speaker output terminals (between + and -).

Idle current Adjustment

Do not connect load to speaker output terminals. Set LEVEL control to minimum (fully counter-clockwise).

Adjust VR₂ for 50mV between terminal No. 26 (+) and No. 16 (-). Confirm that 50mV $\pm$ 10mV appears between terminals No. 25 (+) and No. 17 (-). Readjust after power has been applied for more than 10 minutes.

Power Limiter Adjustment

Connect a 4 ohms resistor and distortion meter, oscilloscope, and AC voltmeter to the speaker output terminals (See Fig. 11). Apply a 1kHz signal to the input terminals and adjust the input signal level for a 200W (28.29V/4 Ω) output. At the same time, adjust VR₃, VR₄ for a distortion of 0.03%. VR₄ adjusts the positive half cycle limiter and VR₃ adjusts the negative half cycle. Observe the waveform with the oscilloscope and adjust so that the waveform is symmetrical.

Fig. 10 Power amplifier

Fig. 11 Connection diagram for power limiter adjustment

8.2 METER AMPLIFIER

Connect an AC voltmeter to the speaker output terminals and apply a 1kHz signal to the input terminals and adjust the input signal level so that the voltmeter indicates 34.64V. At the same time, adjust VR₁ (R channel) and VR₂ (L channel) so that the output meter indicates 0dB.

Fig. 12 The position of VR₁ and VR₂
