

SERVICE MANUAL

PREAMPLIFIER **SANSUI CA-2000**

Sansui

SANSUI ELECTRIC CO., LTD.

This service manual is designed for service engineers to repair, adjust, maintain and order the replacement parts of the CA-2000 correctly. When ordering the parts, use the stock number and parts name specifically referring to the Parts Location and Parts Lists. For general usage and maintenance of the unit, please refer to the Operating Instructions attached with the unit.

2. BLOCK DIAGRAM

3. OPERATIONS OF NEW CIRCUITS

3-1. Current Mirror Circuit

◇Purpose of use in # CA-2000

By adding current mirror section to balanced-type signal amplifier as Fig. 3-1, the current mirror circuit is effective to improve signal to noise ratio, distortion factor and direct current stability.

Fig. 3-1 Current Mirror Circuit on F-2691 Equalizer Circuit Board

◇Advantages

1. By operation of differential amplification in this driver stage, the current mirror circuit is efficient to reduce the influence of the power line voltage deviation and *Common Mode Rejection Ratio (C.M.R.R.).

$$* \text{C.M.R.R. (dB)} = \frac{\text{Differential Gain}}{\text{Common Mode Gain}}$$

2. By basic functions of push-pull amplifier in this circuit, lower distortion factor is obtained.
3. Since the output impedance of this circuit can be kept extremely high, considerable high gain is obtained.

◇Operation

This Current Mirror Circuit is composed of two semiconductors, TR01 & Diode D01 using as the current mirror section, and a IC01 using as the balanced-typed signal amplifier as shown in Fig. 3-1. The transistor, TR01, and transistor A of first stage built in the IC operate as a pushpull amplifier.

◇Phase Characteristics

When input signal shown in Fig. 3-1. is supplied to the base of the transistor A in the IC in normal operation,

1. Out-of phase signal against the input signal appears at the collector of transistor A.
2. In-phase output signal against the input one appears at the emitter of transistor A.
3. Since the base of transistor B built in the IC is grounded in AC equivalent circuit, transistor B operates as the function of common -base circuit; therefore, the signal appeared at collector of transistor B is in-phase signal against signal appeared at emitter of transistor B.
4. The signal appeared at collector of transistor B is given to the base of TR01. The signal appeared at collector of TR01 is out-of phase to the signal at collector of transistor B and is in-phase signal at collector of transistor A.

Thus, the combination of transistor A and TR01 is used as operation of push-pull amplifier.

◇Open Loop Gain

The open loop gain of conventional diffrential amplifier itself is approximately 30dB to 35dB in normal operation; furthermore, by adding the current mirror circuit in series to conventional differential amplifier, it is possible to obtain high open loop gain, approximately 70dB to 80dB. Consquently, the gain 40dB to 50dB, is able to add to negative feedback loop by using the current mirror circuit in order to improve distortion factors.

3-2. Four-gang Level Volume Control

This unit is equipped with four-gang level volume control for the purpose of the following reason.

Conventional 2-channel stereo control amplifier adopts twin (two)-gang level volume control connecting with the input side of tone control circuit. Therefore, noise components existing in equalizer circuit can be gradually decreased by turning level volume control downward, but noises occured in tone control circuit appears direct to output speaker terminals. To eliminate the noises existing in tone control circuit to speaker terminals at a certain low level of volume control, this model, CA-2000 adopts four-gang level volume control which connects with both output and input sides of tone control circuit individually for 2-channel stereo function.

Fig. 3-2 Level Volume Control on one-channel
